hte-package	<i>Hospital transmission estimation</i>
-------------	---

Description

The **hte** package ...

Author(s)

Aaron A. King

abm

*Agent-based colonization/decolonization model***Description**

Given patient movement data, simulated transmission dynamics and screening.

Usage

```
run_abm(
  data,
  b = 0.03,
  gamma = 0.02,
  lambda0 = 0,
  p0 = 0.05,
  alpha = 0.01,
  beta = 0.15,
  adm_eff = 0,
  status_changes = FALSE,
  verbose = getOption("verbose", TRUE)
)
```

Arguments

data	a data frame containing patient movement and testing information. It should have at least the following columns: patient a unique identifier for each patient unit a unique identifier for each unit time a number representing time event a character vector specifying the kind of event: admission, discharge, transfer, or test.
b	transmission rate
gamma	decolonization rate
lambda0	background colonization rate
p0	probability of colonization on admission
alpha, beta	false positive and negative testing error rates
adm_eff	numeric; efficiency of testing on admission
status_changes	logical; should true times of colonization or decolonization events be included in the output?
verbose	run-time information?

Details

`run_abm` simulated the spread of a transmissible agent through a hospital. When testing events are given in `data`, all patients on the given unit are tested. Patients are screened on admission.

Value

run_abm returns a [tibble](#) with one row per testing event. This contains information on the test result, true colonization status, and location of the tested patient.

More on the transmission model: [transmission](#)

Examples

```
## Not run:

library(tidyverse)

expand_grid(
  time=seq(70,1827,by=7),
  unit=LETTERS[1:9],
  event="test"
) -> testsched

sim_pat_mov |>
  bind_rows(testsched) |>
  arrange(time) |>
  run_abm(verbose=TRUE) -> dat

## End(Not run)
```

Bernoulli_filter

Bernoulli filter

Description

Filter the individual patient data with given forces of infection, recovery rates, and test characteristics.

Usage

```
Bernoulli_filter(data, lambda, gamma, theta)
```

```
Bfilter(data, theta)
```

Arguments

data	data set
lambda	unit-specific force of infection
gamma	unit-specific recovery rate
theta	list of parameters

Details

Bernoulli_filter runs a Bernoulli filter, updating the expected prevalence. It returns the log likelihood, occupancy, and expected prevalences.

Bfilter uses an alternative algorithm.

Value

Bernoulli_filter returns a **tibble** containing the expected prevalences (for both isolated and un-isolated patients), unit occupancy, force of infection, and conditional log likelihood for each unit at each event time. The sum of the log likelihood column (logLik) is the log likelihood of the data.

Bfilter returns the log likelihood of the furnished data.

Examples

```
library(tidyverse)

set.seed(626292345)

fake_data |>
  arrange(patient,time) -> dat

theta <- list(
  lambda=c(out=0,A=0.01,B=0.1,C=0.2,D=0.3,E=0.5),
  gamma=c(out=0.1,A=0.1,B=0.1,C=0.1,D=0.1,E=0.1),
  p0=0.2,
  isol_factor=0.1,
  alpha=0.05,
  beta=0.2,
  eta = 0.5
)

dat |>
  Bfilter(theta) -> ll1
sum(ll1)

dat |>
  Bernoulli_filter(
    lambda=theta$lambda,
    gamma=theta$gamma,
    theta
  ) -> f
f |> filter(logLik!=0) |> pull(logLik) -> ll2
sum(ll2)

f

f |>
  select(unit,time,prev_i,prev_u) |>
  pivot_longer(c(prev_i,prev_u)) |>
  group_by(unit) |>
```

```
## prevalence is not estimated outside the hospital
filter(!all(is.na(value))) |>
ungroup() |>
ggplot(aes(x=time,color=name,y=value))+
geom_line(alpha=0.5)+
scale_color_manual(values=c(prev_i="blue",prev_u="red"))+
facet_grid(unit~.,labeller=label_both)+
labs(y="prevalence")+
theme_bw()
```

coal_last

*Coalesce with last***Description**

Fills NA with previous non-NA.

Usage

```
coal_last(x)
```

Arguments

x vector

fake_data

*Fake hospital movement, testing, and isolation data***Description**

Simulated data on patient movement, colonization dynamics, and testing

Details

fake_data was generated by:

```
set.seed(339613584)
simuldat(verbose=TRUE) -> fake_data
save(fake_data,file="fake_data.rda",compress="xz")
```

sim_pat_mov contains simulated patient movement data for a hospital with 800 beds and 40 units.

independent

Independent infection model

Description

Model under which each patient's trajectory of infection is independent, conditional on the force of infection.

Usage

```

indep_homog_filter(params, data)

indep_homog_objfun(params, data, est = character(0))

indep_unit_spec_filter(params, data)

indep_unit_spec_objfun(params, data, est = character(0))

```

Arguments

params	named vector of parameters
data	patient movement, isolation, and testing data
est	names of parameters to estimate

Details

Parameters in the model include:

lambda force of infection. In the homogeneous model, this is constant across units in the hospital; in the unit-specific model, there is one value of lambda for each unit.

lambda.out force of infection outside the hospital

gamma recovery rate

alpha,beta false positive and negative probabilities

p0 probability of infection on admission

isol_factor multiplicative effect of contact isolation on susceptibility

eta additional information on infection status

`indep_homog_filter` runs a Bernoulli filter for the independent model with a global lambda and gamma.

`indep_homog_objfun` is a stateful objective function for the independent model with a global lambda and gamma.

`indep_unit_spec_filter` runs a Bernoulli filter for the independent model with a unit-specific lambda.

`indep_unit_spec_objfun` is a stateful objective function for the independent model with unit-specific lambda.

Examples

```
library(tidyverse)
library(lubridate)
library(pomp)
library(hte)

set.seed(626292345)

## Select some data:
fake_data |>
  filter(
    event!="test" | time < 250,
    time < 1000
  ) |>
  arrange(patient,time) -> dat

## Create an objective function:
indep_homog_objfun(
  params=c(
    lambda.out=0.05,lambda=0.1,gamma=0.01,p0=0.1,
    isol_factor=0.2,alpha=0.02,beta=0.1,eta = 0.5
```

```

    ),
    est=c("lambda", "gamma"),
    data=dat
  ) -> f

## Fit the model:
optim(
  par=log(c(0.1, 0.01)),
  fn=f,
  control=list(reltol=1e-3)
) -> out
f(out$par)
coef(f)

## Examine the filter results:
indep_homog_filter(params=coef(f), data=dat) -> ff
ff |> filter(logLik!=0)

## Construct a slice:
indep_homog_objfun(
  params=coef(f),
  est=c("lambda"),
  data=dat
) -> g

log.lambda <- seq(log(0.001), to=log(1), length=10)
plot(exp(log.lambda), sapply(log.lambda, g), log='x')

## Construct an objective function for the unit-specific model:
theta <- coef(f)
indep_unit_spec_objfun(
  params=c(
    lambda=setNames(rep.int(theta["lambda"], 6), unique(dat$unit)),
    theta[c("p0", "gamma", "alpha", "beta", "isol_factor", "eta")]
  ),
  est=c(
    "lambda.A", "lambda.B", "lambda.C", "lambda.D", "lambda.E", "lambda.out", "gamma"
  ),
  data=dat
) -> h

## Fit the model:
optim(
  par=log(coef(h)[
    c("lambda.A", "lambda.B", "lambda.C", "lambda.D", "lambda.E", "lambda.out", "gamma")
  ]),
  fn=h,
  control=list(reltol=1e-3)
) -> out
h(out$par)
coef(h)

```

simuldat

*simuldat***Description**

simuldat simulates data representing the flow of a body of patients through a hospital over a specified window of time.

simul_patient simulates a single patient's history of movement, testing, isolation, and infection.

Usage

```
simuldat(
  nbeds = c(50, 60),
  arrival = 20,
  window = c("1999-12-31T23:59:59+0000", "2003-01-01T00:00:00+0000"),
  units = list(A = list(shape = 10, scale = 2/10), B = list(shape = 5, scale = 0.5/5), C
    = list(shape = 1, scale = 0.5/1), D = list(shape = 1, scale = 3/1), E = list(shape =
      0.2, scale = 8/0.2), out = list(shape = 0.5, scale = 300/0.5)),
  visits = list(size = 0.5, mu = 9),
  uperv = list(size = 1, mu = 0.5),
  min_dur = 1/24,
  testing_freq = c(A = NA, B = NA, C = 1/7, D = 1/7, E = 1/7, out = NA),
  isolation = list(on = 1/50, off = 1/50),
  infection = list(lambda = c(A = 0.01, B = 0.02, C = 0.001, D = 0.5, E = 0.1, out =
    0.05), gamma = 0.01, p0 = 0.1, isol_factor = 0.2),
  alpha = 0.02,
  beta = 0.1,
  verbose = getOption("verbose", TRUE)
)

simul_patient(
  patient,
  t0,
  tf,
  units,
  visits,
  uperv,
  min_dur,
  testing_freq,
  isolation,
  infection,
  alpha,
  beta
)

indep_infect(lambda, gamma, p0, isol_factor, times, loc, isol)
```

Arguments

nbeds	upper and lower bounds on number of beds
arrival	Poisson arrival rate of new patients
window	window of simulation
units	a named list with one entry per unit. Each entry is itself a list with the parameters of the Gamma-distribution for the duration of stay in the unit.
visits	list containing parameters of a negative binomial distribution for the number of visits per patient.
uperv	list containing parameters for a negative binomial distribution for the number of units visited per visit.
min_dur	minimum duration of stay in any unit
testing_freq	named numeric vector of unit-specific testing frequencies.
isolation	list containing parameters of the isolation model
infection	parameters of the infection model
alpha, beta	false positive and negative testing error rates
verbose	run-time information?
patient	patient name or number
t0, tf	initial and final times of patient itinerary
lambda	force of infection
gamma	recovery rate
p0	initial probability of infection
isol_factor	reduction in susceptibility due to isolation
times	times at which status is reported
loc	location of patient at each time
isol	isolation status

Details

Simulate hospital movement, testing, and isolation data.

Value

infection status vector

stobfun

Stateful objective functions

Description

Convenience functions for constructing and working with stateful objective functions ('stobfun'-class objects).

Usage

```

stobfun(
  embed,
  params,
  est = character(0),
  log = character(0),
  logit = character(0),
  objfun,
  data,
  ...

```

```

)

filterfun(embed, params, filtfun, data, ...)

transf_fns(log = character(0), logit = character(0), est = character(0))

embedding(...)

## S3 method for class 'stobfun'
coef(object, ...)

```

Arguments

embed	embedding (see embedding).
params	vector of parameters
est	character; names of parameters to be estimated
log	character; names of parameters to log transform.
logit	character; names of parameters to logit transform.
objfun	underlying objective function
data	data
...	When furnished to stobfun, additional arguments are passed to objfun. When furnished to embedding, arguments define the embedding. When furnished to coef , additional arguments are ignored.
filtfun	the function that actually applies the filter
object	'stobfun'-class stateful objective function

Details

objfun will be called as `objfun(theta, data)`, where `theta` is the nested list constructed according to the given specifications and `data` is the data.

Value

`transf_fns` returns a list of two functions. The first is the transformation to the estimation scale; the second is its inverse.

`embedding` returns the embedding function corresponding to the given specification.

`coef(f)` returns the parameter vector corresponding to the last call of the stateful objective function `f`.

Construction and usage of stateful objective functions

A stateful objective function is an ordinary function that can be used as an objective function in an optimization problem. In particular, it can be passed to optimizers such as [optim](#), [subplex](#), or [nloptr](#). It is stateful in the sense that it remembers the argument with which it was last called.

To construct a stateful objective function, call the constructor function for the model of interest. The constructor function requires that you pass a vector of model parameters: this gives the default

parameter values. It also requires that you pass the data and the names of the parameters that you wish to estimate. The constructor will return an object of class ‘stobfun’.

Having constructed a ‘stobfun’ stateful objective function, you can pass this to any suitable optimizer. Once the optimizer has returned, **it is important that you call the function one last time, at the parameters the optimizer has returned** (see examples). This ensures that the stored parameters are those at the (putative) optimum. You can retrieve these parameters via a call to `coef`.

See Also

More on stateful objective functions: [independent](#), [transmission](#)

transmission

Transmission model

Description

Model under which the force of infection in each unit is proportional to the prevalence of infection in that unit.

Usage

```
trans_homog_filter(params, data, tol = 1e-04, maxit = 10)

trans_homog_objfun(params, data, est = character(0), tol = 1e-04, maxit = 10)

trans_unit_spec_filter(params, data, tol = 1e-04, maxit = 10)

trans_unit_spec_objfun(
  params,
  data,
  est = character(0),
  tol = 1e-04,
  maxit = 10
)
```

Arguments

<code>params</code>	named vector of parameters
<code>data</code>	patient movement, isolation, and testing data
<code>tol</code>	positive scalar; convergence tolerance (mean difference).
<code>maxit</code>	scalar integer; maximum number of fixed-point iterations. If <code>tol</code> is not achieved in <code>maxit</code> or fewer iterations, an error is generated.
<code>est</code>	names of parameters to estimate

Details

The basic transmission model assumes that the force of infection on an unisolated patient is

$$\lambda = b(P_u + aP_i) + \iota,$$

where P_u , P_i are the prevalences among unisolated and isolated patients, respectively and ι represents the risk of acquisition unrelated to local prevalence. On an isolated patient, this force of infection is reduced by the factor `isol_factor`.

Parameters in the model include:

b transmission rate. In the homogeneous model, this is constant across units in the hospital; in the unit-specific model, there is one value of `b` for each unit.

lambda.out force of colonization outside the hospital

iota baseline force of colonization

gamma recovery rate

alpha,beta false positive and negative probabilities

p0 probability of infection on admission

a multiplicative effect of contact isolation on transmissibility

isol_factor multiplicative effect of contact isolation on susceptibility

eta additional information on infection status

`trans_homog_filter` runs a fixed-point Bernoulli filter for the transmission model with global `b` and `gamma`.

`trans_homog_objfun` is a stateful objective function for the transmission model with global `b` and `gamma`.

`trans_unit_spec_filter` runs a fixed-point Bernoulli filter for the transmission model with unit-specific `b`.

`trans_unit_spec_objfun` is a stateful objective function for the transmission model with unit-specific transmission rates, an out-of-hospital force of infection parameter, and recovery rates that can be different inside and outside of hospital.

Examples

```
library(tidyverse)
library(hte)

set.seed(339613584)

fake_data |>
  ## filter out tests prior to day 250
  filter(
```

```

    event!="test" | time < 250,
    time < 1000
  ) |>
  select(-infected) |>
  arrange(patient,time) -> dat

trans_homog_objfun(
  params=c(
    a=1,b=0.1,gamma=0.01,p0=0.1,lambda.out=0.01,
    iota=0,isol_factor=0.2,alpha=0.02,beta=0.1,eta=0.5
  ),
  est=c("a","b"),
  data=dat
) -> f
f(log(c(0.05,0.4)))
coef(f)

optim(
  par=log(c(0.5,0.4)),
  fn=f,
  control=list(reltol=1e-2)
) -> out
f(out$par)
coef(f)

trans_homog_filter(params=coef(f),data=dat) -> ff
ff |> filter(logLik!=0)

trans_unit_spec_objfun(
  params=c(
    a=1,
    b.A=0.1,b.B=0.1,b.C=0.1,b.D=0.1,b.E=0.1,
    gamma=0.01,p0=0.1,
    lambda.out=0.1,
    iota=0,
    isol_factor=0.2,
    alpha=0.02,beta=0.1,
    eta=0.5
  ),
  data=dat
) -> f
f()
coef(f)

```

twostate

twostate

Description

Two-state Markov process with on and off rates

Usage

```
twostate(on, off, tf, t0 = 0)
```

Arguments

on, off	on and off rates
t0, tf	initial and final times
